FIG. 11B
INFORMATION EXTRACTION FROM A DATABASE

This application claims the benefit of U.S. Provisional Application No. 60/123,583, filed Mar. 10, 1999, which is hereby incorporated by reference.

BACKGROUND OF THE INVENTION

The present invention relates to extracting information from a database. More specifically, the invention relates to searching for tuples of information in order to identify patterns in which the tuples were stored so that additional tuples can be extracted from the database.

The Internet, and more particularly the World Wide Web ("Web"), is a vast repository of information that is extremely distributed, both in the location and manner in which the information is stored. For example, a particular type of data such as restaurant lists may be scattered across thousands of independent information sources (e.g., hosts) in many different formats.

One way that this information is extracted from the Web is by individual users that traverse ("surf") the Web to locate information of interest and manually extract the information. It should be quite evident that this method is very tedious and does not easily provide a comprehensive search. Although multiple users can be employed to perform this manual information extraction, the cost for mining the desired information from the Web is extremely high and does not provide adequate coverage of the Web.

There has also been considerable work on integrating a number of information sources using specially coded wrappers or filters. Although this work has met with some amount of success, the creation of wrappers can be quite time consuming and thus, is usually suited for only tens, not thousands (or more) of information sources. Considering the vast size of the Web and its continual growth, the manual creation of wrappers does not provide an efficient mechanism for extracting information from a database such as the Web.

Therefore, what are needed are innovative techniques for extracting information from databases. Additionally, it would be desirable if the relevant information was extracted from the numerous and distributed information sources automatically or with very minimal human intervention.

SUMMARY OF THE INVENTION

The present invention provides innovative techniques for extracting information and patterns from a database such as the Web. One can begin with one or more tuples of information that act as the initial seed for the search. The database (or databases) is searched for occurrences of the tuples and patterns are identified in which they are stored. These patterns are used to extract more tuples from the database and the process can be repeated for the new tuples. Information can be extracted from a database efficiently and accurately with little or no human interaction. Some specific embodiments of the invention are described below.

In one embodiment, the invention provides a computer implemented method of extracting information from a database. The database is searched for occurrences of at least one tuple of information. An occurrence of a tuple of information that was found is analyzed to identify a pattern in which the tuple of information was stored. Additional tuples of information are extracted from the database utilizing the pattern. In some embodiments, the process is repeated until a predetermined number of tuples are found or until no new patterns are identified.

In another embodiment, the invention provides a computer implemented method of extracting information from a database. The database is searched for occurrences of tuples of information. Occurrences of the tuples of information that were found are analyzed to identify a pattern in which the tuples of information were stored. A pattern includes a prefix text, a middle text and suffix text, where the prefix text precedes desired information in the tuples of information, the middle text is between desired information in the tuples of information and the suffix text follows desired information in the tuples of information. Additional tuples of information are extracted from the database utilizing the pattern and the process is repeated for additional tuples of information.

Other features and advantages of the invention will become readily apparent upon review of the following description in association with the accompanying drawings, where the same or similar structures are designated with the same reference numerals.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates an example of a computer system that can be utilized to execute the software of an embodiment of the invention.

FIG. 2 illustrates a system block diagram of the computer system of FIG. 1.

FIG. 3 illustrates a network of multiple computer systems such as the Internet.

FIG. 4 shows a flow chart of a process of extracting information from a database.

FIG. 5 shows a flow chart of another process of extracting information from a database.

FIG. 6 shows a flowchart of a process of identifying a pattern from tuples of information that have been found in a database.

FIG. 7 shows a flow chart of a process of verifying a tuple of information.

FIG. 8 shows a table of initial tuples of information.

FIG. 9 shows a table of URL patterns and text patterns that were identified from the tuples of information in FIG. 8.

FIG. 10 shows a table of additional tuples of information that were found utilizing the patterns of FIG. 9.

FIGS. 11A and 11B show tables of a portion of the books that were found in this example.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

In the description that follows, the present invention will be described in reference to embodiments that extract information and patterns from the Web. More specifically, the embodiments will be described in reference to utilizing tuples of information to identify patterns in which the tuples are stored so that additional tuples can be found. However, embodiments of the invention are not limited to any particular environment, application or specific implementation. Therefore, the description of the embodiments that follows is for purposes of illustration and not limitation.

FIG. 1 illustrates an example of a computer system that can be used to execute the software of an embodiment of the invention. FIG. 1 shows a computer system 1 that includes a display 3, screen 5, cabinet 7, keyboard 9, and mouse 11. Mouse 11 can have one or more buttons for interacting with
a graphical user interface. Cabinet 7 houses a CD-ROM drive 13, system memory and a hard drive (see FIG. 2) which can be utilized to store and retrieve software programs incorporating computer code that implements the invention, data for use with the invention, and the like. Although CD-ROM 15 is shown as an exemplary computer readable storage medium, other computer readable storage media including floppy disk, tape, flash memory, system memory, and hard drive can be utilized. Additionally, a data signal embodied in a carrier wave (e.g., in a network including the Internet) can be the computer readable storage medium.

FIG. 2 shows a system block diagram of computer system 1 used to execute the software of an embodiment of the invention. As in FIG. 1, computer system 1 includes monitor 3 and keyboard 9, and mouse 11. Computer system 1 further includes subsystems such as a central processor 51, system memory 53, fixed storage 55 (e.g., hard drive), removable storage 57 (e.g., CD-ROM drive), display adapter 59, sound card 61, speakers 63, and network interface 65. Other computer systems suitable for use with the invention can include additional or fewer subsystems. For example, another computer system could include more than one processor 51 (i.e., a multi-processor system) or a cache memory.

The system bus architecture of computer system 1 is represented by arrows 67. However, these arrows are illustrative of any interconnection scheme serving to link the subsystems. For example, a local bus could be utilized to connect the central processor to the system memory and display adapter. Computer system 1 shown in FIG. 2 is but an example of a computer system suitable for use with the invention. Other computer architectures having different configurations of subsystems can also be utilized.

FIG. 3 shows a network of multiple computer systems. A network 101 provides communication between multiple computer systems 1. In a wide area network such as the Internet, some of the computer systems are servers (or hosts) and provide access to resources such as information or services to client computer systems on the network. With respect to the Web, there are thousands of server computer systems that store the web pages that make up the Web. The web pages typically include links in the form of uniform resource locators (URLs) that are a link to another web page, whether it is on the same server or a different one.

As described above, the Web is a distributed network of web pages. Networks of hyperlinked documents can also be present in local area networks (e.g., intranets). The operation of these intranets is very similar to the Internet except that it is not uncommon for all or a majority of the hyperlinked documents of an intranet to be stored on a single server computer system.

In general, embodiments of the invention rely on the duality between patterns and relations, which can be called Dual Iterative Pattern Relation Expansion (DIPRE). Let $D$ be a large database of unstructured information such as the Web. Let $R=r_1, \ldots, r_n$ be the target relation. Every tuple $t$ of $R$ occurs in one or more times in $D$. Every such occurrence consists of all the fields of $t$, represented as strings, occurring in close proximity to each other in $D$ (in the case of the Web, this typically means all the fields are near each other, on the same web page).

As an example, suppose the target relation $R$ is the set of books, with author, title, pairs, that occur on the Web. Thus, the relation $R=(author, title)$, where $r_1=author$ and $r_2=title$. We will call information that may satisfy the relation a "tuple" of information. Accordingly, the tuple ("Isaac Asimov", "The Robots of Dawn") satisfy the relation of books described above. As used herein, a tuple is a set of related information.

Given a potential author and title and where they are mentioned on the Web, a user can generally tell whether this is a legitimate book. However, it would be beneficial if a computer can automatically determine if a potential match has been found and utilize matches to identify other patterns that can then be used to find more matches.

If an approximation $R'$ of $R$ is computed, the coverage is $\frac{|R' \cap R|}{|R'|}$ and the error rate is $\frac{|R' \cap R|}{|R'|}$.

It would be desirable to maximize coverage and minimize the error rate. However, a low error rate may be much more critical than high coverage. Given a sufficiently large database $D$, a recall of just 20% may be acceptable. However, an error rate of 10% would likely be useless for many applications.

With very large databases, it is very difficult, if not impossible, to actually compute $R$. Therefore, it can be difficult to calculate the precise values of coverage and error rate. However, the error rate can be estimated by having a user check random elements of $R'$. Coverage is typically much more difficult to estimate.

Intuitively, a pattern matches one particular format of occurrences of tuples of the target relation. Ideally the pattern is specific enough not to match any tuples that should not be in the relation, however, in practice a few false positives may occur. Patterns may have various representations. For example, patterns may be defined by regular expressions, context free grammars or any computable functions.

Let $p$ be a pattern. Then $M_p(p)$ is the set of tuples that match $p$ in $D$ and $|P|_D$ is the number of elements in $M_p(p)$. Then coverage of $p$, $C_p(p,R)=|M_p(p)\cap R|/|R|$ and the error rate of $p$ is $E_p(p,R)=|M_p(p)\setminus R|/|M_p(p)|$.

For a set of patterns, $P=p_1, \ldots, p_s$, the set of tuples that match the patterns can be defined as $M_P(p)=\bigcup_{p_i \in P} M_{p_i}(p)$. The coverage $C_P(p,R)$ and error rate $E_P(p,R)$ can be extended analogously. Alternative definitions of $M_p(p)$ may require a tuple to match multiple patterns as will be discussed in more detail below.

An important observation is that given a set of patterns $P$ with high coverage and low error rate, a very good approximation to $R$ can be calculated by finding all matches to all the patterns. Thus, given a good set of patterns, a good set of tuples can be found. However, it would be desirable to also achieve the converse property—given a good set of tuples, a good set of patterns can be identified. Both goals can be achieved by finding all occurrences of the tuples in $D$ and discovering similarities in the occurrences. The combination of the ability to find tuples from patterns and patterns from tuples provides great power and is the basis for one aspect of the invention.

FIG. 4 shows a flow chart of a process of extracting information from a database. At a step 201, a search is performed on the database for occurrences of at least one tuple of information. An occurrence of a tuple (or multiple
occurrences of tuples) that was found is analyzed to identify a pattern in which the tuple of information was stored (step 203). At a step 205, additional tuples of information are extracted from the database utilizing the pattern that was identified.

As described, occurrences of tuples can be analyzed to identify patterns, which can then be utilized to extract or find more tuples. The process can then be repeated for the additional tuples. FIG. 5 shows a flow chart of another process of extracting information from a database that illustrates this iterative process.

At a step 301, tuples of information are provided as examples of information that are desired. These initial tuples of information ideally satisfy the target relation and act as a seed from which more tuples of information that satisfy the target relation will be found. Thus, one starts with a small sample R' of the target relation, R'→Sample. Typically, this sample is given by the user and can be very small.

The database is searched for occurrences of the tuples of information at a step 303. This can be expressed as O←FindOccurrences (R'D). In practice, an occurrence is evidenced by fields of the tuples being in fairly close proximity to each other in the text (e.g., the text in HyperText Markup Language or HTML). In preferred embodiments, the context of every occurrence (e.g., URL and surrounding text) is stored along with the tuple found.

At a step 305, the occurrences of the tuples of information that were found in the database are analyzed to identify a pattern in which the tuples of information were stored. In other words, patterns are generated based on the sets of occurrences of tuples, P→GenPatterns (O). Ideally, patterns should be generated for sets of occurrences with similar context. The patterns should have a low error rate so it is important that they are not overly general. The higher the coverage of the patterns the better. However, a low coverage can be compensated for with a larger database.

Additional tuples of information are extracted from the database utilizing the pattern at a step 307. Thus, the database is searched for tuples that match any of the identified patterns, R'→M(P). At a step 309, it is determined if the process is done. If not, the flow returns to step 303 to search for occurrences of the additional tuples of information in the database. The test for whether the process is done can vary in different embodiments. In one embodiment, if R is large enough (e.g., greater than a predetermined number), then the process is done.

The above process is not necessarily very stable and may stray away from R. In particular, several erroneous or bogus tuples in M(P) can lead to several erroneous patterns in P in the next iteration. This in turn can cause a whole slew of erroneous tuples. For this reason, the GenPatterns routine should be careful to minimize the amount of damage caused by a potentially erroneous tuple (or several small tuples).

Another measure of safety is to define M(P) more stringently so as to require tuples to match multiple patterns in P. Although not necessary, the results may improve if tuples are verified more stringently. Finally, the various thresholds may need to fluctuate as the relation expands.

In one embodiment, the patterns that are identified in step 305 are evaluated according to a criteria (e.g., the number of tuples that match each pattern, the specificity of each pattern, and the like). The patterns with the highest evaluation, whether being a predetermined number of patterns, those over a threshold or any other selection mechanism, are processed further. In a similar manner, the tuples of information that are extracted in step 307 can be evaluated according to a criteria (e.g., the number of patterns each tuple matches) and the tuples with the highest evaluation are processed further. As mentioned above, it may be beneficial to vary the thresholds as the relation expands.

FIG. 6 shows a flow chart of a process of verifying a tuple of information that can be performed when additional tuples are extracted from the database utilizing a pattern. At a step 401, the tuple of information that was found utilizing a pattern is checked to see how many patterns the tuple matches. If, at a step 403, the tuple does not match at least the predetermined number of patterns (e.g., more than 1), the tuple is rejected at step 405. Otherwise, the tuple can be accepted at a step 407.

In order to more clearly describe the invention, it may be beneficial to now describe a specific experiment utilizing an embodiment of the invention. In the experiment, it is desired to extract from the Web tuples that satisfy a relation (author, title). In other words, a user would like to extract the authors and titles of books on the Web. This problem lends itself particularly well to the invention because there are a number of well-known books that are listed on many web sites. Many of the web sites conform to a reasonably uniform format across the site.

A pattern is a template for finding additional tuples of information that may satisfy the desired information. A pattern typically needs to be lexically defined because it will be utilized to find the desired information on the books. The lexical definition of a pattern can largely determine how successful the information extraction will be. However, even a very simple lexical definition of a pattern that will be used for this example can generate excellent results. More sophisticated lexical definitions of patterns may provide better results.

In this example, a pattern is a five-tuple of (order, urlprefix, prefix, middle, suffix), where order is a Boolean value and the other attributes are strings. If order is true, the pattern is for an author followed by a title. Otherwise, if order is false, the title precedes the author.

An (author, title) pair matches the pattern if there is a document in the collection (e.g., the Web) with a URL that matches urlprefix* and which contains text that matches the regular expression: *prefix, author, middle, title, suffix*. It should be understood that prefix is text that preceeds desired information in the tuples of information, middle is text between desired information tuples of information and suffix is text that follows desired information tuples of information. With this simple example, there is only one middle, but the invention can be advantageously applied to extracting information with more than two fields and the number of middle texts in the patterns can be similarly increased.

In the experiment, the author was restricted to [A-Za-z. &]+ [A-Za-z.] and the title was restricted to [A-Za-z0-9]+ [A-Za-z0-9]+ [A-Za-z0-9]+. These express simply define the strings of characters that will be allowed to make up an author and title, respectively, and will be utilized during a lexical search of the Web for tuples of information. In other embodiments, the expressions can be varied accordingly.

An occurrence can be lexically defined in correspondence to the definition of a pattern. An occurrence of an (author, title) pair can consist of a seven-tuple: (author, title, order, urlprefix, middle, suffix). The order corresponds to the order the author and title occurred in the text. The url is the URL of the document in which the they occurred. The prefix includes the m characters (e.g., 10 preceding the author (or title if the title was first). The middle is the text between the author and the title. Lastly, the suffix includes the m characters following the title (or author). In other embodiments,
the prefix and suffix can be different lengths. Additionally, the prefix and suffix can be less than m characters if the line ends or starts close to the occurrence.

Now that examples of patterns and occurrences have been described, a process of generating patterns, GenPatterns(O), will be described. Initially, all occurrences o in O are grouped by order and middle. In other words, in each group, the values for the fields' order and middle are the same. The resulting groups shall be designated O₁, . . . , Oₐ. The occurrences in each group can then be analyzed to identify a pattern as follows.

FIG. 7 shows a flow chart of a process of identifying a pattern in multiple occurrences. At a step 501, the order and middle text are checked to verify that they are the same between or among the occurrences. If they are determined to not be the same at a step 503, then no pattern is identified at a step 505. It is nearly impossible to generate a pattern to match all the occurrences if the order and middle text are not the same. If the groups have been assembled accordingly to the same order and middle text, steps 501, 503 and 505 may not be necessary. The order and middle fields of the pattern can be set according to the group. As with any of the flow chart in this section, steps can be added, deleted, combined, and reordered without departing from the spirit and scope of the invention.

At a step 507, the longest matching URL prefix of the occurrences in the group is set to the field urprefix of the pattern. The longest matching prefix text of the occurrences in the group is set to the field prefix at a step 509. At a step 511, the longest matching suffix text of the occurrences in the group is set to the field sufix.

The specificity of the pattern can be checked at a step 513. A pattern generated like the above can be too general or too specific. In general, it is not a concern to be too specific since there will be many patterns generated and combined there will be many books. However, if the pattern is too general, many nonbooks may be found.

In order to increase the accuracy, the specificity of the pattern is measured. The specificity of a pattern p can roughly correspond to \(-\log(P(XeMₙ,p)))\) where X is some random variable distributed uniformly over the domain of tuples of R. If the domain is infinite like the space of all strings, the uniform distribution may not be sensible and a different distribution should probably be used.

For quick computation, specificity of a pattern \(p₁\) depends on the length of \(s₁\) can be calculated by the following:

\[
specificity(p₁) = p₁.middle * p₁.urprefix * p₁.prefix * p₁.suffix\]

In other words, the specificity of the pattern is determined by the product of the lengths of the strings that make up the pattern. This ensures that all the strings of a pattern are nonempty (otherwise the specificity is zero).

Patterns with too low a specificity can be rejected so that overly general patterns are not generated. More specifically, patterns can only be accepted if their specificity(p) > t where n is the number of books with occurrences supporting the pattern p and t is a threshold (e.g., a predetermined specificity). Thus, the specificity increases in proportion to the number of tuples that match the pattern. Also, n > 1 should be true since basing a pattern on one example is very error-prone. As described above, the process can be complete when a predetermined number of tuples of information are extracted. Additionally, the process can complete when there are no more patterns identified that have a specificity greater than a predetermined specificity.

Returning to step 515, if the specificity is less than a predetermined specificity, then no pattern is identified at step 505. In a preferred embodiment, an additional check is performed. If all the occurrences in the group do not have the same URL, then the URL prefix is shortened until the group can be broken into more than one group. Each of these new groups can be processed by returning to step 501 and proceeding as described above. Thus, a simple further subdivision based on the URL can be used when the pattern is generated is not sufficiently specific. Additionally, the prefix and/or suffix text can be used for subdivisions.

An important aspect of the invention is the GenPatterns routine that takes a set of occurrences of books, in this example, and converts them into a list of patterns. This is a nontrivial problem and there is a literature filled of pattern recognition devoted to solving the general version of this problem. However, a simple set of heuristics for generating patterns from occurrences can be utilized with excellent results. As long as there are a few false positives (patterns that generate nonbooks), this is sufficient. Each pattern need only have a very small coverage since the Web is vast and there are many sources of information so the total coverage of all the patterns can still be perfect.

With regard to performance, there are two very demanding tasks—finding occurrences of books given a long list of books and finding pattern matches given a list of patterns. Both of these operations may take place over a very large database of Web documents.

For the first task of finding occurrences of books, finding occurrences of books, the data was passed through two grep filters. One filter only passed through lines that contained a valid author and the other filter only passed through lines that contained a valid title. After this, it is the task of a program written in Python to actually check that there are matching authors and titles in the line, identify them and produce occurrences as output. Several alternative approaches involving large regular expressions in Flex and in Python were attempted for this purpose but they quickly exceed various internal bounds.

For the second task of finding pattern matches, a Python program was used. Every pattern was translated into a pair of regular expressions, one for the URL and one for the actual occurrence. Every URL was first tested to see which patterns apply to it. Then the program tests every line for the relevant regular expressions. This approach can be fairly slow so future versions may likely to use Flex or rex C library. This task can be made somewhat easier by targeting just the URLs that match the pattern. However, the data is not structured to make that completely trivial and it would be desirable to develop techniques that are general enough to be able to handle no restrictions on URLs.

The generation of patterns from occurrences is not much of a performance issue with this example because there are only thousands of occurrences generated. As larger extractions are performed, this will likely become more important. Currently, the occurrences are sorted using gsort by order and middle. The Python program reads through the resulting list and generates the patterns.

Returning to the example of finding books by (author, title) pairs, an initial set of five books was used as the seed. The (author, title) pairs for these books are shown in the table in FIG. 8. For a database, a repository of 24 million web pages totaling 147 gigabytes was used. This data is part of the Stanford WebBase and is used for the Google search engine, which includes an embodiment of the invention. As a part of the search engine, an inverted index of the entire repository was built.

The repository spans many disks and several machines. It takes a considerable amount of time to make just one pass over the data even without doing any substantial processing.
Therefore, passes were only made over subsets of the repository on any given iteration. It should be noted that the repository contains almost no web pages from Amazon because their automatically generated URLs make crawling difficult.

A search for occurrences of tuples of information for the five books in FIG. 8 produced 199 occurrences and generated three patterns. The three patterns are shown in a table in FIG. 9. Interestingly, only the first two of the five books produced the patterns because they were both science fiction books. A run of these patterns over matching URLs produced 947 unique (author, title) pairs. These additional tuples were mostly science fiction by there were some exceptions. FIG. 10 shows a sample of books that were found using the three patterns from FIG. 9.

A search through roughly 5 million web pages for the additional tuples of information found 3972 occurrences of these books. These occurrences produced 105 patterns, 24 of which had URL prefixes which were not complete URLs. A pass over a couple million URLs produced 9369 unique (author, title) pairs. There were some erroneous books among these. For example, 242 of the occurrences had legitimate titles but books, some were obscure or out of print and some simply were not listed on some sites for no apparent reason.

It is interesting to note that in total, 5 of the 20 books were not on Amazon’s web site, which claims to have a catalog of 2.5 million books.

Some books are mentioned several times due to small differences such as capitalization, spacing, and how the author was listed (for example “E. R. Burroughs” versus “Edgar Rice Burroughs”). Fortunately, however, authors are quite particular about how their name is listed and these duplications are limited. In several cases, some information was appended to the author’s name such as publication date.

It would be desirable to be able to extract structured data from the entire Web by leveraging on its vastness. Embodiments of the invention have proven to be a remarkable tool in the simple example of finding lists of books. It started with a sample set of five books and expanded it to a relatively high quality list of over 15,000 books with very minimal human intervention. The same tool may be applied to a number of other domains such as movies, music, restaurants, product directories, product catalogs, and more.

One challenge is to prevent or hinder divergence from the target as the relation is expanded. For example, since two science fiction books were in the seed sample, it is fairly surprising that the expansion did not produce a large list of science fiction books. Clearly, the expansion gravitated to a compilation of all books and even a few scattered articles managed to enter the relation. Keeping this effect under control as the relation expands is nontrivial but there are several possibilities.

One possibility is to redefine $M_r(P)$ to require multiple patterns to match a tuple. A more extreme version of this is to assign a weight simultaneously with one relation influencing another. For example, a relation First-(first name) includes recognized first names of people and a relation Last-(last name) includes recognized last names of people. The First and Last relations can be initialized any number of ways including utilizing the information extraction techniques described above. In this example, the First and Last relations are initialized with the first and last names of a few authors. When tuples of information are extracted that satisfy the relation Author-(first name, last name), a test is performed to verify that either the first name or the last name of each tuple satisfies the relation First or Last, respectively. If one of the First or Last relations is satisfied, the tuple is accepted. The corresponding first or last name of each accepted tuple can then be added to the appropriate relation First or Last in order to simultaneously grow the relations.

In other embodiments, the relations may not grow simultaneously, such as when one or more of the relations is initialized to a state that should remain unchanged. It should be noted that the relations utilized herein are fairly simple for purposes of illustration, but the relations may include more fields in practice.

While the above is a complete description of preferred embodiments of the invention, various alternatives,
modifications, and equivalents can be used. It should be
evident that the invention is equally applicable by making
appropriate modifications to the embodiments described
above. Therefore, the above description should not be taken
as limiting the scope of the invention that is defined by the
mistes and bounds of the appended claims along with their
full scope of equivalents.
What is claimed is:
1. A computer implemented method of extracting inform-
ation from a database, comprising:
searching the database for occurrences of at least one
tuple of information;
analyzing an occurrence of a tuple of information that was
found in the database to identify a pattern in which the
tuple of information was stored; and
extracting additional tuples of information from the data-
bases utilizing the pattern.
2. The method of claim 1, further comprising providing
the at least one tuple of information as an example of
information that is desired.
3. The method of claim 1, further comprising repeating
the searching, analyzing and extracting for additional tuples
of information.
4. The method of claim 3, wherein the repeating the
searching, analyzing and extracting for the additional tuples
of information continues until a predetermined number of
tuples of information are extracted.
5. The method of claim 1, wherein the pattern is defined
by a regular expression, context free grammar or computable
function.
6. The method of claim 1, wherein the pattern includes a
middle text, where the middle text is between desired
information in the tuples of information.
7. The method of claim 1, wherein the pattern includes a
prefixed text and a suffix text, where the prefix text proceeds
desired information in the tuples of information and the
suffix text follows desired information in the tuples of
information.
8. The method of claim 1, wherein the pattern includes an
order of the information in each tuple of information.
9. The method of claim 1, wherein the pattern includes a
URL prefix, where the URL prefix is the initial portion of the
URL where the pattern was identified.
10. The method of claim 1, further comprising verifying
if an additional tuple of information matches a predeter-
mined number of patterns, wherein the predetermined
number of patterns is greater than 1.
11. The method of claim 10, wherein the additional tuple
is rejected if it does not match at least the predetermined
number of patterns.
12. The method of claim 1, further comprising verifying
if the pattern has a specificity less than a predetermined
specificity.
13. The method of claim 12, wherein the pattern is
rejected if the specificity is less than the predetermined
specificity.
14. The method of claim 12, further comprising repeating
the searching, analyzing and extracting for additional tuples
of information, wherein the searching, analyzing and
extracting for the additional tuples of information continues
until no more patterns are identified that have a specificity
greater than the predetermined specificity.
15. The method of claim 12, further comprising calculat-
ing the specificity by multiplying text string lengths of
components of the pattern.
16. The method of claim 12, wherein the specificity
increases in proportion to the number of tuples of informa-
tion that match the pattern.
17. The method of claim 1, wherein the database is the
World Wide Web.
18. A computer program product for extracting informa-
tion from a database, comprising:
computer code that searches the database for occurrences
of at least one tuple of information;
computer code that analyzes an occurrence of a tuple of
information that was found in the database to identify
a pattern in which the tuple of information was stored;
computer code that extracts additional tuples of informa-
tion from the database utilizing the pattern; and
a computer readable medium that stores the computer
codes.
19. The computer program product of claim 18, wherein
the computer readable medium is a CD-ROM, floppy disk,
tape, flash memory, system memory, hard drive, or data
signal embodied in a carrier wave.
20. A computer implemented method of extracting informa-
tion from a database, comprising:
searching the database for occurrences of tuples of informa-
tion;
analyzing the occurrences of the tuples of information that
were found in the database to identify a pattern in which
the tuples of information were stored, wherein a pattern
includes a prefix text, a middle text and a suffix text, where
the prefix text precedes desired information in the
in the tuples of information, the middle text is between
desired information in the tuples of information and the
suffix text follows desired information in the tuples of
information;
extracting additional tuples of information from the data-
bases utilizing the pattern; and
repeating the searching, analyzing and extracting for
additional tuples of information.
21. The method of claim 20, further comprising providing
the tuples of information as examples of information that are
desired.
22. The method of claim 20, wherein the repeating of the
searching, analyzing and extracting for the additional tuples
of information continues until a predetermined number of
tuples of information are extracted.
23. The method of claim 20, wherein the pattern includes an
order of the information in the tuples of information.
24. The method of claim 20, wherein the pattern includes a
URL prefix, where the URL prefix is the initial portion of the
URL where the pattern was identified.
25. The method of claim 20, further comprising verifying
if an additional tuple of information matches a predeter-
mined number of patterns, wherein the predetermined
number of patterns is greater than 1.
26. The method of claim 20, further comprising verifying
if the pattern has a specificity less than a predetermined
specificity.
27. The method of claim 25, wherein the additional tuple
is rejected if it does not match at least the predetermined
number of patterns.
28. The method of claim 26, wherein the pattern is
rejected if the specificity is less than the predetermined
specificity.
29. The method of claim 26, further comprising repeating
the searching, analyzing and extracting for additional tuples
of information, wherein the searching, analyzing and
extracting for the additional tuples of information continues
until no more patterns are identified that have a specificity
greater than the predetermined specificity.
30. The method of claim 26, further comprising calculat-
ing the specificity by multiplying text string lengths of
components of the pattern.
31. The method of claim 26, wherein the specificity increases in proportion to the number of tuples of information that match the pattern.

32. The method of claim 20, wherein the database is the World Wide Web.

33. A computer program product for extracting information from a database, comprising:
   - computer code that searches the database for occurrences of tuples of information;
   - computer code that analyzes the occurrence of tuples of information that were found in the database to identify a pattern in which the tuples of information were stored, wherein a pattern includes a prefix text, a middle text and suffix text, where the prefix text precedes desired information in the tuples of information,
   - the middle text is between desired information in the tuples of information and the suffix text follows desired information in the tuples of information;
   - computer code that extracts additional tuples of information from the database utilizing the pattern;
   - computer code that repeats the searching, analyzing and extracting for additional tuples of information; and
   - a computer readable medium that stores the computer codes.

34. The computer program product of claim 33, wherein the computer readable medium is a CD-ROM, floppy disk, tape, flash memory, system memory, hard drive, or data signal embodied in a carrier wave.
